#### Lecture #11

- Bell-LaPadula model
  - Formal: more mathematical one (but still a lattice!)

#### Basic Security Theorem

- Define action, secure formally
  - Using a bit of foreshadowing for "secure"
- Restate properties formally
  - Simple security condition
  - \*-property
  - Discretionary security property
- State conditions for properties to hold
- State Basic Security Theorem

#### Action

- A request and decision that causes the system to move from one state to another
  - Final state may be the same as initial state
- $(r, d, v, v') \in R \times D \times V \times V$  is an *action* of  $\Sigma(R, D, W, z_0)$  iff there is an  $(x, y, z) \in \Sigma(R, D, W, z_0)$  and a  $t \in N$  such that  $(r, d, v, v') = (x_t, y_t, z_t, z_{t-1})$ 
  - Request r made when system in state v; decision d moves system into (possibly the same) state v'
  - Correspondence with  $(x_t, y_t, z_t, z_{t-1})$  makes states, requests, part of a sequence

# Simple Security Condition

- $(s, o, p) \in S \times O \times P$  satisfies the simple security condition relative to f (written  $ssc \ rel \ f$ ) iff one of the following holds:
  - 1.  $p = \underline{e}$  or  $p = \underline{a}$
  - 2.  $p = \underline{\mathbf{r}} \text{ or } p = \underline{\mathbf{w}} \text{ and } f_s(s) \ dom f_o(o)$
- Holds vacuously if rights do not involve reading
- If all elements of b satisfy ssc rel f, then state satisfies simple security condition
- If all states satisfy simple security condition, system satisfies simple security condition

#### Necessary and Sufficient

- $\Sigma(R, D, W, z_0)$  satisfies the simple security condition for any secure state  $z_0$  iff for every action (r, d, (b, m, f, h), (b', m', f', h')), W satisfies
  - Every  $(s, o, p) \in b b'$  satisfies ssc relf
  - Every  $(s, o, p) \in b'$  that does not satisfy *ssc rel f* is not in b
- Note: "secure" means  $z_0$  satisfies ssc rel f
- First says every (s, o, p) added satisfies ssc rel f; second says any (s, o, p) in b' that does not satisfy ssc rel f is deleted

# \*-Property

- $b(s: p_1, ..., p_n)$  set of all objects that s has  $p_1, ..., p_n$  access to
- State (b, m, f, h) satisfies the \*-property iff for each  $s \in S$  the following hold:
  - 1.  $b(s: \underline{\mathbf{a}}) \neq \emptyset \Rightarrow [\forall o \in b(s: \underline{\mathbf{a}}) [f_o(o) dom f_c(s)]]$
  - 2.  $b(s: \underline{\mathbf{w}}) \neq \emptyset \Rightarrow [\forall o \in b(s: \underline{\mathbf{w}}) [f_o(o) = f_c(s)]]$
  - 3.  $b(s: \underline{r}) \neq \emptyset \Rightarrow [\forall o \in b(s: \underline{r}) [f_c(s) dom f_o(o)]]$
- Idea: for writing, object dominates subject; for reading, subject dominates object

# \*-Property

- If all states satisfy simple security condition, system satisfies simple security condition
- If a subset S' of subjects satisfy \*-property, then \*-property satisfied relative to  $S' \subseteq S$
- Note: tempting to conclude that \*-property includes simple security condition, but this is false
  - See condition placed on w right for each

#### Necessary and Sufficient

- $\Sigma(R, D, W, z_0)$  satisfies the \*-property relative to  $S' \subseteq S$  for any secure state  $z_0$  iff for every action (r, d, (b, m, f, h), (b', m', f', h')), W satisfies the following for every  $s \in S'$ 
  - Every  $(s, o, p) \in b b'$  satisfies the \*-property relative to S'
  - Every  $(s, o, p) \in b'$  that does not satisfy the \*-property relative to S' is not in b
- Note: "secure" means  $z_0$  satisfies \*-property relative to S'
- First says every (s, o, p) added satisfies the \*-property relative to S'; second says any (s, o, p) in b' that does not satisfy the \*-property relative to S' is deleted

# Discretionary Security Property

- State (b, m, f, h) satisfies the discretionary security property iff, for each  $(s, o, p) \in b$ , then  $p \in m[s, o]$
- Idea: if s can read o, then it must have rights to do so in the access control matrix m
- This is the discretionary access control part of the model
  - The other two properties are the mandatory access control parts of the model

#### Necessary and Sufficient

- $\Sigma(R, D, W, z_0)$  satisfies the ds-property for any secure state  $z_0$  iff, for every action (r, d, (b, m, f, h), (b', m', f', h')), W satisfies:
  - Every  $(s, o, p) \in b b'$  satisfies the ds-property
  - Every  $(s, o, p) \in b'$  that does not satisfy the ds-property is not in b
- Note: "secure" means  $z_0$  satisfies ds-property
- First says every (s, o, p) added satisfies the dsproperty; second says any (s, o, p) in b' that does not satisfy the \*-property is deleted

#### Secure

- A system is secure iff it satisfies:
  - Simple security condition
  - \*-property
  - Discretionary security property
- A state meeting these three properties is also said to be secure

#### Basic Security Theorem

- $\Sigma(R, D, W, z_0)$  is a secure system if  $z_0$  is a secure state and W satisfies the conditions for the preceding three theorems
  - The theorems are on the slides titled "Necessary and Sufficient"

#### Rule

- $\rho: R \times V \to D \times V$
- Takes a state and a request, returns a decision and a (possibly new) state
- Rule  $\rho$  *ssc-preserving* if for all  $(r, v) \in R \times V$  and v satisfying *ssc rel* f,  $\rho(r, v) = (d, v')$  means that v' satisfies *ssc rel* f'.
  - Similar definitions for \*-property, ds-property
  - If rule meets all 3 conditions, it is *security-preserving*

#### Unambiguous Rule Selection

- Problem: multiple rules may apply to a request in a state
  - if two rules act on a read request in state v ...
- Solution: define relation  $W(\omega)$  for a set of rules  $\omega$  = {  $\rho_1, ..., \rho_m$  } such that a state  $(r, d, v', v) \in W(\omega)$  iff either
  - $-d = \underline{\mathbf{i}}$ ; or
  - for exactly one integer j,  $\rho_i(r, v) = (d, v')$
- Either request is illegal, or only one rule applies

#### Rules Preserving SSC

- Let  $\omega$  be set of *ssc*-preserving rules. Let state  $z_0$  satisfy simple security condition. Then  $\Sigma(R, D, W(\omega), z_0)$  satisfies simple security condition
  - Proof: by contradiction.
    - Choose  $(x, y, z) \in \Sigma(R, D, W(\omega), z_0)$  as state not satisfying simple security condition; then choose  $t \in N$  such that  $(x_t, y_t, z_t)$  is first appearance not meeting simple security condition
    - As  $(x_t, y_t, z_t, z_{t-1}) \in W(\omega)$ , there is unique rule  $\rho \in \omega$  such that  $\rho(x_t, z_{t-1}) = (y_t, z_t)$  and  $y_t \neq \underline{i}$ .
    - As  $\rho$  ssc-preserving, and  $z_{t-1}$  satisfies simple security condition, then  $z_t$  meets simple security condition, contradiction.

# Adding States Preserving SSC

- Let v = (b, m, f, h) satisfy simple security condition. Let  $(s, o, p) \notin b, b' = b \cup \{ (s, o, p) \}$ , and v' = (b', m, f, h). Then v' satisfies simple security condition iff:
  - 1. Either  $p = \underline{e}$  or  $p = \underline{a}$ ; or
  - 2. Either  $p = \underline{\mathbf{r}}$  or  $p = \underline{\mathbf{w}}$ , and  $f_c(s)$  dom  $f_o(o)$
  - Proof
    - 1. Immediate from definition of simple security condition and v' satisfying  $ssc\ rel\ f$
    - 2. v' satisfies simple security condition means  $f_c(s)$   $dom f_o(o)$ , and for converse,  $(s, o, p) \in b'$  satisfies  $ssc \ rel \ f$ , so v' satisfies simple security condition

# Rules, States Preserving \*Property

• Let  $\omega$  be set of \*-property-preserving rules, state  $z_0$  satisfies \*-property. Then  $\Sigma(R, D, W(\omega), z_0)$  satisfies \*-property

# Rules, States Preserving ds-Property

• Let  $\omega$  be set of ds-property-preserving rules, state  $z_0$  satisfies ds-property. Then  $\Sigma(R, D, W(\omega), z_0)$  satisfies ds-property

# Combining

- Let  $\rho$  be a rule and  $\rho(r, v) = (d, v')$ , where v = (b, m, f, h) and v' = (b', m', f', h'). Then:
  - 1. If  $b' \subseteq b, f' = f$ , and v satisfies the simple security condition, then v' satisfies the simple security condition
  - 2. If  $b' \subseteq b$ , f' = f, and v satisfies the \*-property, then v' satisfies the \*-property
  - 3. If  $b' \subseteq b$ ,  $m[s, o] \subseteq m'[s, o]$  for all  $s \in S$  and  $o \in O$ , and v satisfies the ds-property, then v' satisfies the ds-property

- 1. Suppose *v* satisfies simple security property.
  - a)  $b' \subseteq b$  and  $(s, o, \underline{\mathbf{r}}) \in b'$  implies  $(s, o, \underline{\mathbf{r}}) \in b$
  - b)  $b' \subseteq b$  and  $(s, o, \underline{\mathbf{w}}) \in b'$  implies  $(s, o, \underline{\mathbf{w}}) \in b$
  - c) So  $f_c(s)$  dom  $f_o(o)$
  - d) But f' = f
  - e) Hence  $f'_{c}(s) dom f'_{o}(o)$
  - f) So v'satisfies simple security condition
- 2, 3 proved similarly

# Example Instantiation: Multics

- 11 rules affect rights:
  - set to request, release access
  - set to give, remove access to different subject
  - set to create, reclassify objects
  - set to remove objects
  - set to change subject security level
- Set of "trusted" subjects  $S_T \subseteq S$ 
  - \*-property not enforced; subjects trusted not to violate
- $\Delta(\rho)$  domain
  - determines if components of request are valid

#### get-read Rule

- Request r = (get, s, o, <u>r</u>)
  s gets (requests) the right to read o
- Rule is  $\rho_1(r, v)$ : if  $(r \neq \Delta(\rho_1))$  then  $\rho_1(r, v) = (\underline{i}, v)$ ; else if  $(f_s(s) \ dom \ f_o(o) \ and \ [s \in S_T \ or \ f_c(s) \ dom \ f_o(o)]$ and  $r \in m[s, o]$ ) then  $\rho_1(r, v) = (y, (b \cup \{(s, o, \underline{r})\}, m, f, h))$ ; else  $\rho_1(r, v) = (\underline{n}, v)$ ;

#### Security of Rule

- The get-read rule preserves the simple security condition, the \*-property, and the ds-property
  - Proof
    - Let v satisfy all conditions. Let  $\rho_1(r, v) = (d, v')$ . If v' = v, result is trivial. So let  $v' = (b \cup \{ (s_2, o, \underline{\mathbf{r}}) \}, m, f, h)$ .

- Consider the simple security condition.
  - From the choice of v', either  $b' b = \emptyset$  or  $\{(s_2, o, \underline{\mathbf{r}})\}$
  - If  $b'-b=\emptyset$ , then  $\{(s_2, o, \underline{\mathbf{r}})\} \in b$ , so v=v', proving that v' satisfies the simple security condition.
  - If  $b'-b = \{ (s_2, o, \underline{\mathbf{r}}) \}$ , because the *get-read* rule requires that  $f_c(s) \ dom \ f_o(o)$ , an earlier result says that v' satisfies the simple security condition.

- Consider the \*-property.
  - Either  $s_2 \in S_T$  or  $f_c(s)$  dom  $f_o(o)$  from the definition of get-read
  - If  $s_2 \in S_T$ , then  $s_2$  is trusted, so \*-property holds by definition of trusted and  $S_T$ .
  - If  $f_c(s)$  dom  $f_o(o)$ , an earlier result says that v' satisfies the simple security condition.

- Consider the discretionary security property.
  - Conditions in the *get-read* rule require  $\underline{\mathbf{r}} \in m[s, o]$  and either  $b' b = \emptyset$  or  $\{(s_2, o, \underline{\mathbf{r}})\}$
  - If  $b'-b=\emptyset$ , then  $\{(s_2, o, \underline{\mathbf{r}})\} \in b$ , so v=v', proving that v' satisfies the simple security condition.
  - If  $b'-b = \{ (s_2, o, \underline{\mathbf{r}}) \}$ , then  $\{ (s_2, o, \underline{\mathbf{r}}) \} \notin b$ , an earlier result says that v' satisfies the ds-property.

#### give-read Rule

- Request  $r = (s_1, give, s_2, o, \underline{\mathbf{r}})$ 
  - $-s_1$  gives (request to give)  $s_2$  the (discretionary) right to read o
  - Rule: can be done if giver can alter parent of object
    - If object or parent is root of hierarchy, special authorization required

#### Useful definitions

- root(o): root object of hierarchy h containing o
- parent(o): parent of o in h (so  $o \in h(parent(o))$ )
- canallow(s, o, v): s specially authorized to grant access when object or parent of object is root of hierarchy
- $-m \wedge m[s,o] \leftarrow \underline{r}$ : access control matrix m with  $\underline{r}$  added to m[s,o]

#### give-read Rule

• Rule is  $\rho_6(r, v)$ : if  $(r \neq \Delta(\rho_6))$  then  $\rho_6(r, v) = (\underline{i}, v)$ ; else if  $([o \neq root(o) \text{ and } parent(o) \neq root(o) \text{ and } parent(o) \in b(s_1:\underline{w})]$  or  $[parent(o) = root(o) \text{ and } canallow(s_1, o, v)]$  or  $[o = root(o) \text{ and } canallow(s_1, o, v)]$ ) then  $\rho_6(r, v) = (y, (b, m \land m[s_2, o] \leftarrow \underline{r}, f, h))$ ; else  $\rho_1(r, v) = (\underline{n}, v)$ ;

#### Security of Rule

- The *give-read* rule preserves the simple security condition, the \*-property, and the ds-property
  - Proof: Let v satisfy all conditions. Let  $\rho_1(r, v) = (d, v')$ . If v' = v, result is trivial. So let  $v' = (b, m[s_2, o] \leftarrow \underline{r}, f, h)$ . So b' = b, f' = f, m[x, y] = m'[x, y] for all  $x \in S$  and  $y \in O$  such that  $x \neq s$  and  $y \neq o$ , and  $m[s, o] \subseteq m'[s, o]$ . Then by earlier result, v' satisfies the simple security condition, the \*-property, and the ds-property.

# Principle of Tranquility

- Raising object's security level
  - Information once available to some subjects is no longer available
  - Usually assume information has already been accessed, so this does nothing
- Lowering object's security level
  - The declassification problem
  - Essentially, a "write down" violating \*-property
  - Solution: define set of trusted subjects that sanitize or remove sensitive information before security level lowered

# Types of Tranquility

#### Strong Tranquility

 The clearances of subjects, and the classifications of objects, do not change during the lifetime of the system

#### • Weak Tranquility

 The clearances of subjects, and the classifications of objects, do not change in a way that violates the simple security condition or the \*-property during the lifetime of the system

# Example of Weak Tranquility

- Only one subject at TOP SECRET
- Document at CONFIDENTIAL
- New CONFIDENTIAL user to be added
  - User should not see document
- Raise document to SECRET
  - Subject still cannot write document
  - All security relationships unchanged

#### Declassification

- Lowering the security level of a document
  - Direct violation of the "no writes down" rule
  - May be necessary for legal or other purposes
- Declassification policy
  - Part of security policy covering this
  - Here, "secure" means classification changes to a lower level in accordance with declassification policy

# Principles

- Principle of Semantic Consistency
  - You can change parts of a system not involved in declassification without affecting security
- Principle of Occlusion
  - Declassification cannot conceal *improper* lowering of security levels

#### Principles

- Principle of Conservativity
  - Absent any declassification, the system is secure
- Principle of Monotonicity of Release
  - Declassifying information in accordance with the declassification policy does not make the system less secure

# Principle of Semantic Consistency

- As long as the semantics of the parts of the system not involved in the declassification do not change, those parts may be changed without affecting system security
  - No leaking due to semantic incompatibilities
  - Delimited release: allow declassification,
    release of information only through specific channels ("escape hatches")

### Principle of Occlusion

- Declassification mechanism cannot conceal *improper* lowering of security levels
  - Robust declassification property: attacker cannot use escape hatches to obtain information unless it is properly declassified

### Other Principles

- Principle of Conservativity
  - Absent declassification, system is secure
- Principle of Monotonicity of Release
  - When declassification is performed in an authorized manner by authorized subjects, the system remains secure

Idea: declassifying information in accordance with declassification policy does not affect security

### Controversy

#### • McLean:

- "value of the BST is much overrated since there is a great deal more to security than it captures. Further, what is captured by the BST is so trivial that it is hard to imagine a realistic security model for which it does not hold."
- Basis: given assumptions known to be nonsecure, BST can prove a non-secure system to be secure

### †-Property

- State (b, m, f, h) satisfies the  $\dagger$ -property iff for each  $s \in S$  the following hold:
  - 1.  $b(s: \underline{\mathbf{a}}) \neq \emptyset \Rightarrow [\forall o \in b(s: \underline{\mathbf{a}}) [f_c(s) dom f_o(o)]]$
  - 2.  $b(s: \underline{\mathbf{w}}) \neq \emptyset \Rightarrow [\forall o \in b(s: \underline{\mathbf{w}}) [f_o(o) = f_c(s)]]$
  - 3.  $b(s: r) \neq \emptyset \Rightarrow [\forall o \in b(s: r) [f_c(s) dom f_o(o)]]$
- Idea: for writing, subject dominates object; for reading, subject also dominates object
- Differs from \*-property in that the mandatory condition for writing is reversed
  - For \*-property, it's object dominates subject

### Analogues

#### The following two theorems can be proved

- $\Sigma(R, D, W, z_0)$  satisfies the †-property relative to  $S' \subseteq S$  for any secure state  $z_0$  iff for every action (r, d, (b, m, f, h), (b', m', f', h')), W satisfies the following for every  $s \in S'$ 
  - Every  $(s, o, p) \in b b'$  satisfies the †-property relative to S'
  - Every  $(s, o, p) \in b'$  that does not satisfy the †-property relative to S' is not in b
- $\Sigma(R, D, W, z_0)$  is a secure system if  $z_0$  is a secure state and W satisfies the conditions for the simple security condition, the  $\dagger$ -property, and the ds-property.

### Problem

- This system is *clearly* non-secure!
  - Information flows from higher to lower because of the †-property

### Discussion

- Role of Basic Security Theorem is to demonstrate that rules preserve security
- Key question: what is security?
  - Bell-LaPadula defines it in terms of 3 properties (simple security condition, \*-property, discretionary security property)
  - Theorems are assertions about these properties
  - Rules describe changes to a particular system instantiating the model
  - Showing system is secure requires proving rules preserve these 3 properties

#### Rules and Model

- Nature of rules is irrelevant to model
- Model treats "security" as axiomatic
- Policy defines "security"
  - This instantiates the model
  - Policy reflects the requirements of the systems
- McLean's definition differs from Bell-LaPadula
  - ... and is not suitable for a confidentiality policy
- Analysts cannot prove "security" definition is appropriate through the model

### System Z

- System supporting weak tranquility
- On *any* request, system downgrades *all* subjects and objects to lowest level and adds the requested access permission
  - Let initial state satisfy all 3 properties
  - Successive states also satisfy all 3 properties
- Clearly not secure
  - On first request, everyone can read everything

### Reformulation of Secure Action

- Given state that satisfies the 3 properties, the action transforms the system into a state that satisfies these properties and eliminates any accesses present in the transformed state that would violate the property in the initial state, then the action is secure
- BST holds with these modified versions of the 3 properties

### Reconsider System Z

- Initial state:
  - subject s, object o
  - $C = \{ High, Low \}, K = \{ All \}$
- Take:
  - $-f_c(s) = (\text{Low}, \{\text{All}\}), f_o(o) = (\text{High}, \{\text{All}\})$
  - $m[s, o] = \{ \underline{w} \}, \text{ and } b = \{ (s, o, \underline{w}) \}.$
- s requests <u>r</u> access to o
- Now:

$$-f'_{o}(o) = (Low, {All})$$

$$-(s, o, \underline{\mathbf{r}}) \in b', m'[s, o] = \{\underline{\mathbf{r}}, \underline{\mathbf{w}}\}$$

### Non-Secure System Z

- As  $(s, o, \underline{r}) \in b' b$  and  $f_o(o)$  dom  $f_c(s)$ , access added that was illegal in previous state
  - Under the new version of the Basic Security
    Theorem, System Z is not secure
  - Under the old version of the Basic Security Theorem, as  $f'_c(s) = f'_o(o)$ , System Z is secure

# Response: What Is Modeling?

- Two types of models
  - 1. Abstract physical phenomenon to fundamental properties
  - 2. Begin with axioms and construct a structure to examine the effects of those axioms
- Bell-LaPadula Model developed as a model in the first sense
  - McLean assumes it was developed as a model in the second sense

# Reconciling System Z

- Different definitions of security create different results
  - Under one (original definition in Bell-LaPadula Model), System Z is secure
  - Under other (McLean's definition), System Z is not secure
